DETAILED ACTION

Interview Summary

During telephone interview with Mr. George O. Saile on July 9, 2002, Applicants cancel claim 1.

Election/Restrictions

Applicant's election with traverse of claims 23-27 in Paper No. 6 is acknowledged. The traversal is on the ground(s) that the increased cost applicant would be forced to bear and the field of search must be necessarily cover all species. This is not found persuasive because using a hard mask in conjunction with double layer of low dielectric constant material in second species is distinct and mutually exclusive from the first species of using adhesion promoting layer over the low dielectric constant material without a hard mask. And, the third species of using a hard mask layer over an anti-reflective layer and chemical mechanical polishing the low dielectric constant material prior to forming an adhesion layer is distinct and mutually exclusive from the first species of using adhesion promoting layer over the non-planarized low dielectric constant material and without a hard mask over the anti-reflective layer. Since, all species are distinct and mutually exclusive, therefore, there is no reason why a search for first species must include a search for second or third species as well. The existence of three distinct species provides evidence of burden on the examiner in examining the inventions. (see MPEP §§ 803.02, 802.01, 806.04, 808.01-808-02, 806.5-806.5(i)).

Art Unit: 2813

The requirement is still deemed proper and is therefore made FINAL.

Claims 28-41 are withdrawn from further consideration pursuant to 37 CFR 1.142(b), as being drawn to a non-elected with traverse, there being no allowable generic or linking claim.

Applicant timely traversed the restriction (election) requirement in Paper No. 6.

Drawings

Acknowledge the formal drawings filed 5/1/01 has been accepted and approved.

Claim Rejections - 35 USC § 103

The following is a quotation of 35 U.S.C. 103(a) which forms the basis for all obviousness rejections set forth in this Office action:

(a) A patent may not be obtained though the invention is not identically disclosed or described as set forth in section 102 of this title, if the differences between the subject matter sought to be patented and the prior art are such that the subject matter as a whole would have been obvious at the time the invention was made to a person having ordinary skill in the art to which said subject matter pertains. Patentability shall not be negatived by the manner in which the invention was made.

Claims 23, 25, and 27 are rejected under 35 U.S.C. 103(a) as being unpatentable over Jeng et al. (U.S. Patent No. 6,114,186) in view of Lucas (U.S. Patent No. 6,287,951).

Referring to figures 1-3, Jeng et al.'186 teaches a method for fabricating multilevel metal interconnections having low dielectric constant insulators on a substrate comprising the steps of providing first metal lines (14), formed over the substrate (10),

Art Unit: 2813

coating a layer of low dielectric constant insulating material (18) on and in between the metal lines (14, col. 4, lines 31-38),

curing the low dielectric constant insulating material (18) by cured at about 300°C by a hot plate bake on the spin-coater (see col. 4, lines 39-42),

depositing a thin layer of stabilizing material (20, a silicon nitride which is a non-oxide compound, as claimed in claim 25) over the low dielectric constant insulating material layer (18), by plasma with the thickness of about 1,000-3,000A°, (see col. 4, lines 42-60),

depositing a cap silicon oxide layer (22) by PECVD with the thickness about 16,000A° on the stabilizing layer (20), (as claimed in claim 27),

planarizing the silicon oxide cap layer (22) by CMP (see col. 4, lines 61-67), repeating above steps to form multiple levels of interconnections (see col. 5, lines 6-12).

Jeng et al.'186 teaches that silicon nitride layer is used as a stabilizing layer, but fails to teach that silicon nitride can be used as an adhesion promoter layer as well. Nevertheless, such processing step is known in the semiconductor processing art as evidenced by Lucas. Lucas teaches forming a silicon nitride adhesion layer (32) over low dielectric constant insulator material layer (26) (see col.5, lines 1-13). It would have been obvious to a person of ordinary skill in the art at the time the invention was made to have used the silicon nitride layer both as an adhesion promoter layer and stabilizing layer in Jeng et al.'s process as taught by Lucas *because* inserting the silicon nitride layer between the cap silicon oxide layer and the underlying low dielectric constant material layer would eliminate the adhesion problem when cap silicon oxide layer formed over the underlying low dielectric constant material layer.

Art Unit: 2813

Claim 24 is rejected under 35 U.S.C. 103(a) as being unpatentable over Jeng et al. (U.S. Patent No. 6,114,186) in view of Lucas (U.S. Patent No. 6,287,951) as applied to claims 23, 25, 27, further in view of You et al. (U.S. Patent No. 6,197,703).

Jeng et al. '186 in view of Lucas does not specifically show curing the low dielectric material in the conditions at 400°C for 1 hr., in a nitrogen ambient gas flow from about 1 to 30 SLM, oxygen less than 10 ppm (as required by claim 24). Nevertheless, such processing steps are known in the semiconductor processing art as evidenced by You et al. You et al. teaches forming a low dielectric constant material layer HSQ (24, see figure 1), which is a spin-on dielectric layer, and curing the low dielectric constant material layer HSQ (24) by baking in an oven in an inert gas (which includes nitrogen gas) ambient at 400°C for an hour (see col. 5, lines 10-21).

It would have been obvious to a person of ordinary skill in the art at the time the invention was made to cure the low dielectric constant layer in a nitrogen gas ambient in Jeng et al.'s process as taught by You et al. *because* curing the low dielectric constant material layer HSQ at 400°C for 1 hr., in a nitrogen gas ambient would form a layer of low dielectric constant material layer containing lower moisture/solvent in the material, therefore, it increases the adhesion strength when overlying layer is formed on the surface, and it also improves the surface uniformity and planarization.

It would also have been obvious to a person of ordinary skill in the art at the time the invention was made that there is no oxygen in the inert gas ambient or vacuum because You et al. teaches curing the low dielectric constant material layer HSO in an inert gas ambient or

Art Unit: 2813

vacuum (see col. 5, lines 16-18), therefore, the oxygen content must be less than 10 ppm in an inert gas ambient or vacuum (as required by claim 24).

The specific gas flow range of the nitrogen gas as claimed are taken to be obvious since these are variables of art recognized importance which are subject to routine experimentation and optimization and discovery of an optimum value for a known process is obvious. In re Aller, 105 USPQ 233 (CCPA 1955). And, even if applicants' modification results in great improvement and utility over the prior art, it may still not be patentable if the modification was within the capabilities of one skilled in the art, In Re Sola 25 USPQ 433.

Therefore, one of ordinary skill in the requisite art at the time the invention was made would have used specific nitrogen gas flow range to cure the HSQ low dielectric constant material which has a thickness of greater 4000 angstroms (see col. 5, lines 26-35 of Jeng et al. '186) *because* using specific nitrogen flow rate would decrease the drying time for the solvent in the HSQ material layer to evaporate out of the material, and with the combination of specific nitrogen gas flow rate, film thickness and curing temperature could also cause the HSQ material to reflow and filling the wafer's channel.

Claim 26 is rejected under 35 U.S.C. 103(a) as being unpatentable over Jeng et al. (U.S. Patent No. 6,114,186) in view of Lucas (U.S. Patent No. 6,287,951) as applied to claims 23, 25, 27, further in view of Jeng et al. (U.S. Patent No. 5,818,111).

Jeng et al. '186 in view of Lucas does not specifically show the thickness of the silicon nitride layer between about 200-500 A° (as required by claim 26). Nevertheless, such processing steps are known in the semiconductor processing art as evidenced by Jeng et al. '111 (see figures

Art Unit: 2813

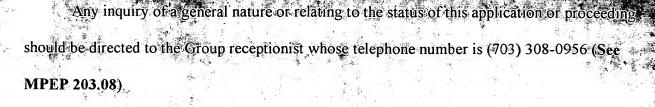

1, 5), Jeng et al. '111 teaches a method for fabricating multilevel metal interconnections having low dielectric constant insulators on a substrate comprising the steps of: providing first metal lines (14), formed over the substrate (10), coating a layer of low dielectric constant insulating material HSQ (18) over and in between the metal lines (14), depositing a thin layer of a stabilizing material (20, Si₃N₄) by plasma (also known as plasma enhanced chemical vapor deposition) with the thickness of about 100-3000 A° (see col. 4, lines 25-28).

It would have been obvious to a person of ordinary skill in the art at the time the invention was made to deposit a thin layer of stabilizing material by plasma with the thickness of about 100-3000 A° in the process of Jeng et al.'186 as taught by Jeng et al.'111 *because* silicon nitride with a specific range of thickness would prevent the moisture in the ambient diffuse into the low dielectric constant material HSQ layer, therefore, a more stable layer of HSQ material with higher degree of adhesion property and less moisture content in the material can be achieved.

Conclusion

Any inquiry concerning this communication or earlier communications from the examiner should be directed to Thanh Nguyen whose telephone number is (703) 308-9439, or by Email via address Thanh.Nguyen@uspto.gov. The examiner can normally be reached on Monday-Thursday from 7:00AM to 5:30PM.

If attempts to reach the examiner by telephone are unsuccessful, the examiner's supervisor, Olik Chaudhuri, can be reached on (703) 306-2794. The fax phone number for this Group is (703) 308-7722.
